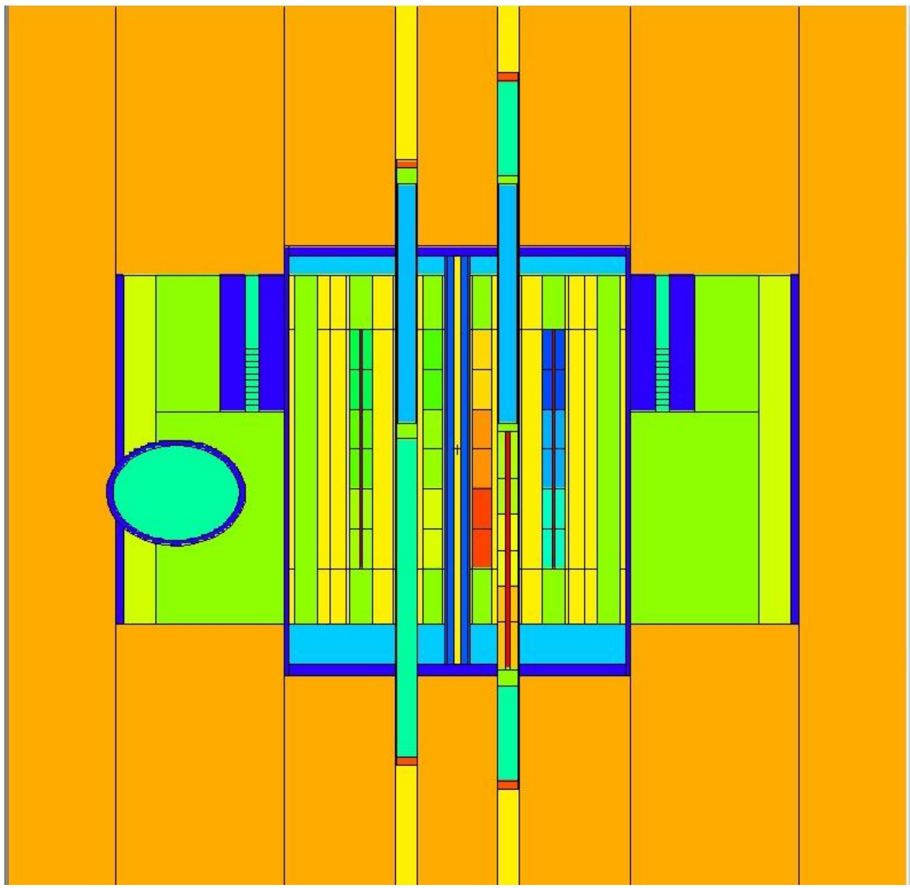
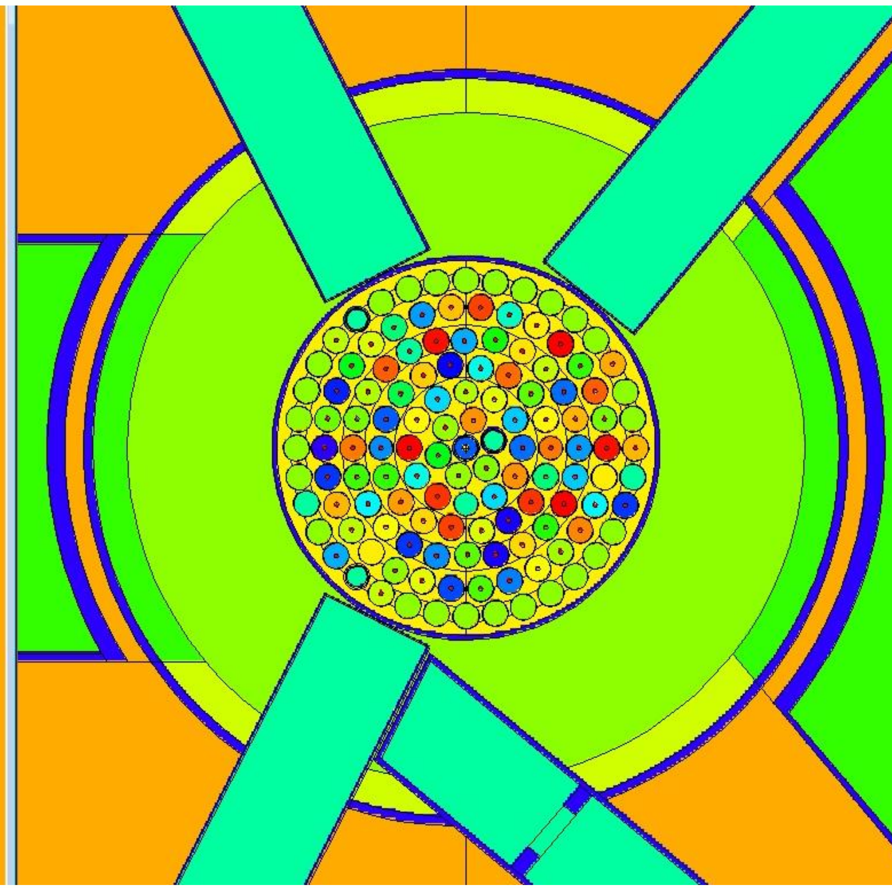
Criticality Modeling of the Oregon State TRIGA Reactor Utilizing the MCNP6 BURN Option

Robert Schickler





History

- OSTR MCNP model originally written by Kanokrat Tiyapun in 1997 in support of boron neutron capture therapy research
- OSTR converted from HEU to LEU in 2008
- 1997 MCNP model was used for various analyses in support of LEU conversion

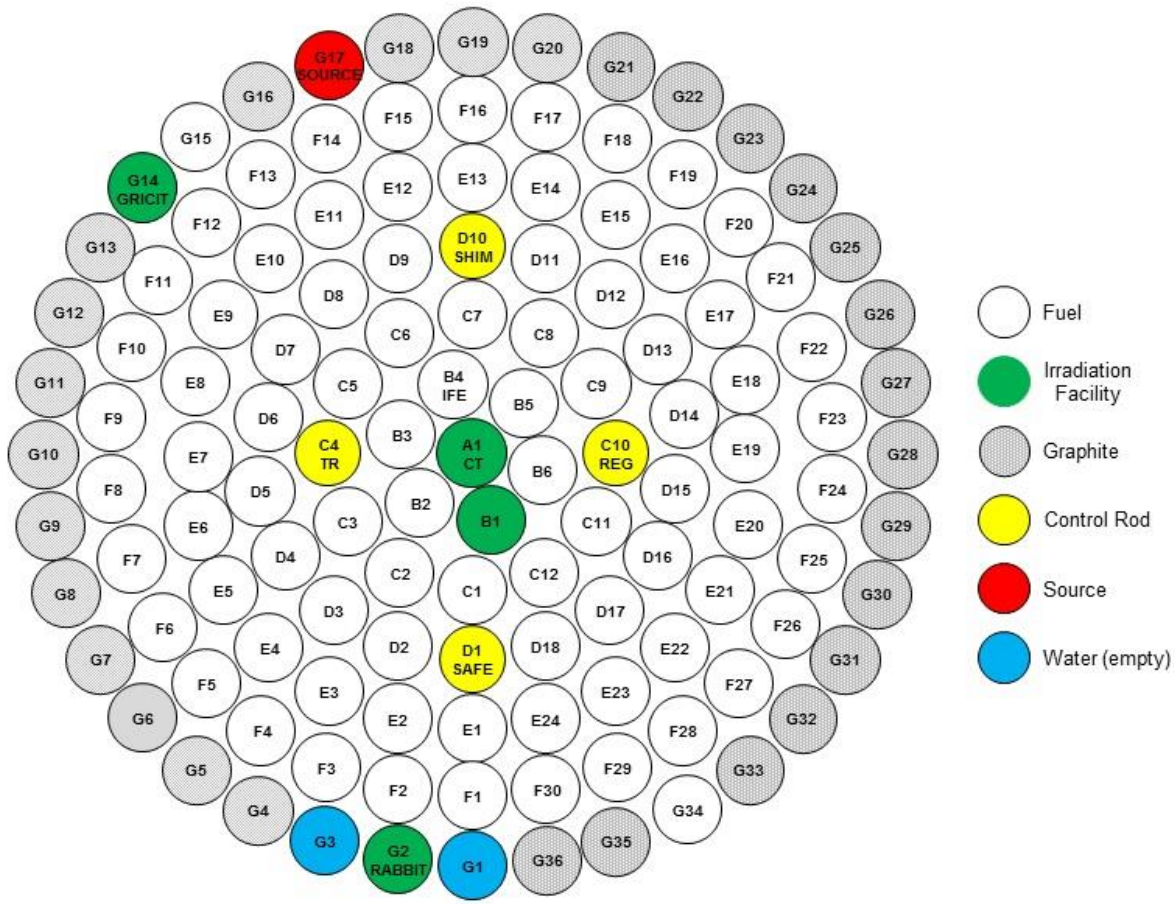
  - Accurately predicted critical mass (predicted 69 FEs, actual was 67 FEs)

  - Accurately predicted control rod worth:

Control Rod	Measured Rod Worth [$]	MCNP5 Predicted Rod Worth [$]
Shim Rod	2.76 ± 0.14	2.55 ± 0.16
Safety Rod	2.66 ± 0.13	2.60 ± 0.16
Regulating Rod	3.71 ± 0.19	3.36 ± 0.19
Transient Rod	2.86 ± 0.14	2.86 ± 0.15
Sum of all Rods	11.99 ± 1.68	11.37 ± 0.33

Oregon State UNIVERSITY

Current OSTR Core Configuration



Motivation

- MCNP model needs to be updated in support of future projects, such as medical isotope production
- No longer accurate due to 8 years of fuel burnup and changes to the facility (new reflector/Rabbit facility installed in 2013)
- Using fresh fuel isotopics with actual critical rod height data from December 2013 yielded excessive reactivity:

Core Configuration	Power	k-effective	Reactivity
Normal	15 W	1.01343	$1.77
	1 MW	1.01068	$1.41
ICIT	15 W	1.01307	$1.72
	1 MW	1.00959	$1.27
CLICIT	15 W	1.01266	$1.67
	1 MW	1.00915	$1.21

Oregon State UNIVERSITY

Motivation

Improvements to the original MCNP model

- Updated material cards from ENDF/B-VI cross section libraries to ENDF/B-VII.1
- Updated fuel material cards using information from CERCA, with spectrometric data that greatly improved atomic fraction accuracy
- Modeled OSTR at low power (15 W) using .80c cross sections and full power (1 MW) using mostly .81c cross sections for in-core materials that would experience approximately 300°C

← Time step in days

← Fraction of power (100%)

← Power in MW

← Each number represents one-third of a fuel element

← Determines which fission products output

Oregon State UNIVERSITY

Procedure

Basic procedure for burnup calculations

- Determine a starting point
  - Use critical rod height data from reactor operation (as close to "cold, clean core" as possible)
- Perform a burnup calculation for a determined amount of time based upon power history (power logs)
  - I coincided each time step to our annual control rod calibrations
- After the burnup calculation is complete, depleted fuel isotopics must be parsed from the large (70 MB of text) output file then reinserted into the original deck
- Control rod heights must be changed to reflect the new core

Oregon State University

Procedure

Step 1 – Refine model to reflect fresh fuel core conditions in 2008

- Challenge – Reflector was filled with water, which altered reactivity
- Allyson Kitto’s 2012 thesis determined reactivity bias of reflector by changing reflector material: “sweet spot” was 70% graphite, 30% water
- Using this reflector material, as well as accurate fuel isotopics from CERCA, and actual critical rod data at low power (15W) and full power (1 MW) yielded the following reactivity values:

Date	Core Configuration	Power	k-effective	Reactivity
2008	Normal	15W	1.00031	$0.04
		1MW	1.00083	$0.11
	ICIT	15W	1.00096	$0.13
		1MW	1.00121	$0.16
	CLICIT	15W	0.99977	-$0.03
		1MW	0.99992	-$0.01

Oregon State UNIVERSITY

Procedure

Step 2 – Perform burnup of fuel from 2008 to 2013

- From power history, fuel experienced approximately 260 MW-days of burnup
- One 260 day time step was performed to burn fuel
- Challenge – sacrifice accuracy for time efficiency
  - Burnup calculation is a slow process
    - A calculation using only one time step took 8.5 days to run using 50,000 neutrons per cycle
    - Burnup is currently unable to utilize multi-threading/MPI
  - OSTR has multiple core configurations, but over 90% of operations are performed in one configuration (CLICIT), so burnup calculation was performed in this configuration

Procedure

Step 2 – Perform burnup of fuel from 2008 to 2013

- After burnup calculation is completed, the resulting depleted fuel isotopics are re-inserted into the model, reflector was changed to non-water-filled, Rabbit was changed to titanium, and critical rods heights from December 2013 were used to determine criticality

Date	Core Configuration	Power	k-effective	Reactivity	Fresh Fuel Reactivity
2013	Normal	15W	1.00115	$0.15	$1.77
		1MW	0.99961	-$0.05	$1.41
	ICIT	15W	0.99966	-$0.05	$1.72
		1MW	0.99886	-$0.15	$1.27
	CLICIT	15W	0.99928	-$0.10	$1.67
		1MW	0.99743	-$0.34	$1.21

Oregon State UNIVERSITY

Procedure

Step 3 – Perform burnup of fuel from 2013 to 2014

- From power history, fuel experienced approximately 44.5 MW-days of burnup, thus one 44.5 day time step was performed
- Resulting fuel isotopics were again inserted into the model and benchmarked against critical rod heights in 2014:

Date	Core Configuration	Power	k-effective	Reactivity
2014	Normal	15W	1.00004	$0.01
		1MW	0.99926	-$0.10
	ICIT	15W	1.00015	$0.02
		1MW	0.99889	-$0.15
	CLICIT	15W	1.00046	$0.06
		1MW	0.99884	-$0.15

Oregon State University

Procedure

Step 4 – Perform burnup of fuel from 2014 to 2015

- From power history, fuel experienced approximately 56.8 MW-days of burnup, thus one 56.8 day time step was performed
- Resulting fuel isotopics were again inserted into the model and benchmarked against critical rod heights in 2015:

Date	Core Configuration	Power	k-effective	Reactivity
2015	Normal	15W	1.00081	$0.11
		1MW	0.99958	-$0.06
	ICIT	15W	1.00137	$0.18
		1MW	0.99924	-$0.10
	CLICIT	15W	1.00085	$0.11
		1MW	0.99842	-$0.21

Results

- The end result is a model that appears to be a far more accurate representation of the state of the OSTR
- Uranium/plutonium buildup and depletion can now be tracked
- A power-per-element history can be produced to show how power changes throughout the core over core life
- Burnup calculations will be performed every year to keep the model as accurate as possible

Future Work

Now that the fuel isotopics are more accurate, various analyses are planned:

- Core optimization is currently being analyzed, with potential fuel shuffling to optimize the efficiency of in-core irradiation facilities
- Current project being explored is a 2nd CLICIT irradiation facility on the core periphery
  - Initial numbers indicate flux is 3-4 times lower on the core periphery, but this is acceptable for short irradiations

Oregon State UNIVERSITY

Acknowledgments

- Dr. Kanokrat Tiyapun for writing the original MCNP model
- Allyson Kitto for her help with determining reflector bias
- Tommy Holschuh for help with Perl script writing for parsing
- Drs. Mike Fensin and Forrest Brown at LANL for assistance with understanding how to use the MCNP burn option
